Preface

Chemical processes provide a diverse array of valuable products and materials used in applications ranging from health care to transportation and food processing. Yet these same chemical processes that provide products and materials essential to modern economies also generate substantial quantities of wastes and emissions. Managing these wastes costs tens of billions of dollars each year, and as emission and treatment standards continue to become more stringent, these costs will continue to escalate. In the face of rising costs and increasingly stringent performance standards, traditional end-of-pipe approaches to waste management have become less attractive and a strategy variously known as environmentally conscious manufacturing, eco-efficient production, or pollution prevention has been gaining prominence. The basic premise of this strategy is that avoiding the generation of wastes or pollutants can often be more cost effective and better for the environment than controlling or disposing of pollutants once they are formed.

The intent of this textbook is to describe environmentally preferable or "green" approaches to the design and development of processes and products. The idea of writing this textbook was conceived in 1997 by the staff of the Chemical Engineering Branch (CEB), Economics, Exposure and Technology Division (EETD), Office of Pollution Prevention and Toxics (OPPT) of the US EPA. In 1997, OPPT staff found that, although there was a growing technical literature describing "green" approaches to chemical product and process design, and a growing number of university courses on the subject, there was no standard textbook on the subject area of green engineering.

So, in early 1998, OPPT initiated the Green Engineering Project with the initial goal of producing a text describing "green" design methods suitable for inclusion in the chemical engineering curriculum.

Years of work, involving extensive interaction between chemical engineering educators and EPA staff, have resulted in this text. The text presents the "green" engineering tools that have been developed for chemical processes and is intended for senior-level chemical engineering students. The text begins (Chapters 1-4) with a basic introduction to environmental issues, risk concepts, and environmental regulations. This background material identifies the types of wastes, emissions, material use, and energy use to determine the environmental performance of chemical processes and products. Once the environmental performance targets have been defined, the design of processes with superior environmental performance can begin. Chapters 5-12 describe tools for assessing and improving the environmental performance of chemical processes. The structure of the chapters revolves around a hierarchy of design, beginning with tools for evaluating environmental hazards of chemicals, continuing through unit operation and flowsheet analysis, and concluding with the economics of environmental improvement projects. The final section of the text (Chapters 13 and 14) describes tools for improving product stewardship and improving the level of integration between chemical processes and other material processing operations.

It is our hope that this text will contribute to the evolving process of environmentally conscious design.

Draft manuscripts of this text have been used in senior-level engineering elective and required courses at the University of Texas at Austin, Michigan Technological University, the University of South Carolina, and West Virginia University. It is suggested, in a typical semester, all of the material in the text is presented. Portions of the textbook have been and can be used in a number of other chemical engineering courses as well as other engineering or environmental policy courses. Dr. David T. Not the best book I've ever used.

By Ian M. Peek

I used this book for a graduate level course, "Advances in Pollution Prevention". This book is not the best book I've ever read. The end-of chapter problems are mediocre, and often insult the reader's ability, particularly as a graduate level chemical engineering student. One example that comes to mind is where the problem requests the student to "write a 2 page essay" on some topic or another. It could use a lot more "meat" - stronger use of reaction kinetics, thermodynamics, and transport phenomena. The writing is difficult to follow, and sounds like a government report (not surprising, as the authors work for the EPA).

Interesting book for all you GREEN folks

By Idorenyin Luke

This is a good book. If you need to know where environmental protection fits into engineering studies and design, then this book is for you.

moderately over priced text

By Michael Clauson

A bit of a quandary: needed for class, but disagree with the premise that CO₂ is all man caused. It is not. Even at less than 0.03 percent of the atmosphere, the oceans stabilize the concentration better than

sequestration. THE text DOES introduce proper stewardship of resources by renaming the term "sustainability."
